Options and padding :::																															

For Mcast, use an Mcast address which identifies n PE's but use an option that identifies which PE's have been visited.
e.g option initially set to 64(1'001) by source, each PE router maps Mcast address to a 64 bit field, then AND's with option field
Each PE will clear its bit in the option field

If all columns are allowed to run asynchronously, do we need a means to identify when a WU is complete before another can start.
Perhaps have a 64 element WU complete field in a WU descriptor that each column sets???? rambling

Maybe we should have a global and a local sync, a layer complete would be a global sync where one layer doesn't start untilthe previous layer is complete.

3DIC Cell-Based DataFlow Processor Communication Cell Formats

Control/Data Cells : The cell sizes below over worst case sizes. For example, we allocate space for up to 64K nodes on 256 chains.

In practice as shown in the examples, these sizes would be much lower.

In the case of sparsey or ConvNet, they can be ROI's or Kernels.

For Sparsey, we might have 100 MAC's with 1000 cells resulting in 100,000 WID's for layer0.

For ConvNet, we might have 96 kernels each operating on an ROI

Each WID specifies Tag for Cell weight matrix and argTag for the ROI

Result Comm Cells

Request Comm Cells

Work-Unit Control
Total Bits = 256/cell

dest chain	Node ID	Work ID	sdp	pdp	p	rel	SG	ELS	Tag
argTag	Size (bytes)	outTag	outIndex	outStagger	ack				

We will likely need to send "sync" commands to PE's with info such as which PE's to synchronize to.
In these cases, a single large cell will be inefficient from a bandwidth perspective. For FIFO's, we have already sized them for data cells.
We need to balance comm logic complexity versus efficiency and latency of control messages.
So perhaps we should balance this by having two lengths, one for control/special and one for data.

Work-Unit Control/Data
Total Bits = 1280/cell

Used if :

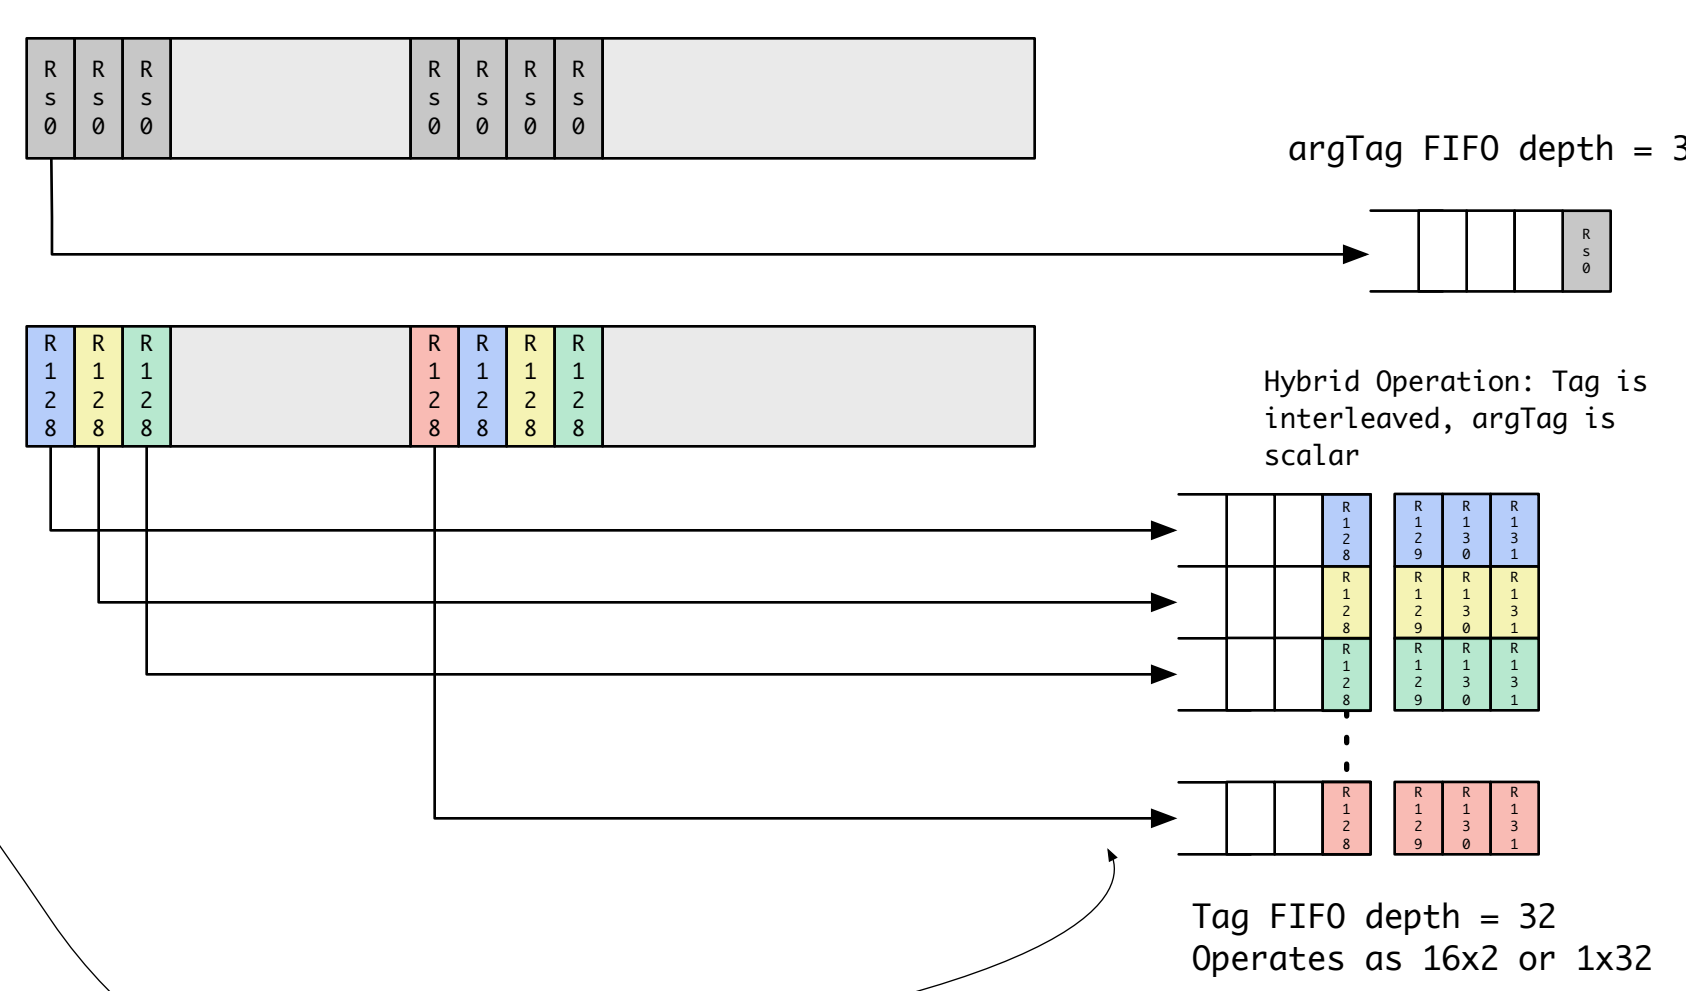

- Tag data wholly contained in cell. argTag can still be streaming if sdp is valid
- sdp is write to shmem (2-words of data saved to each Exec Lanes shared memory)

Request Data
Total Bits = 1152/cell

128b/16b

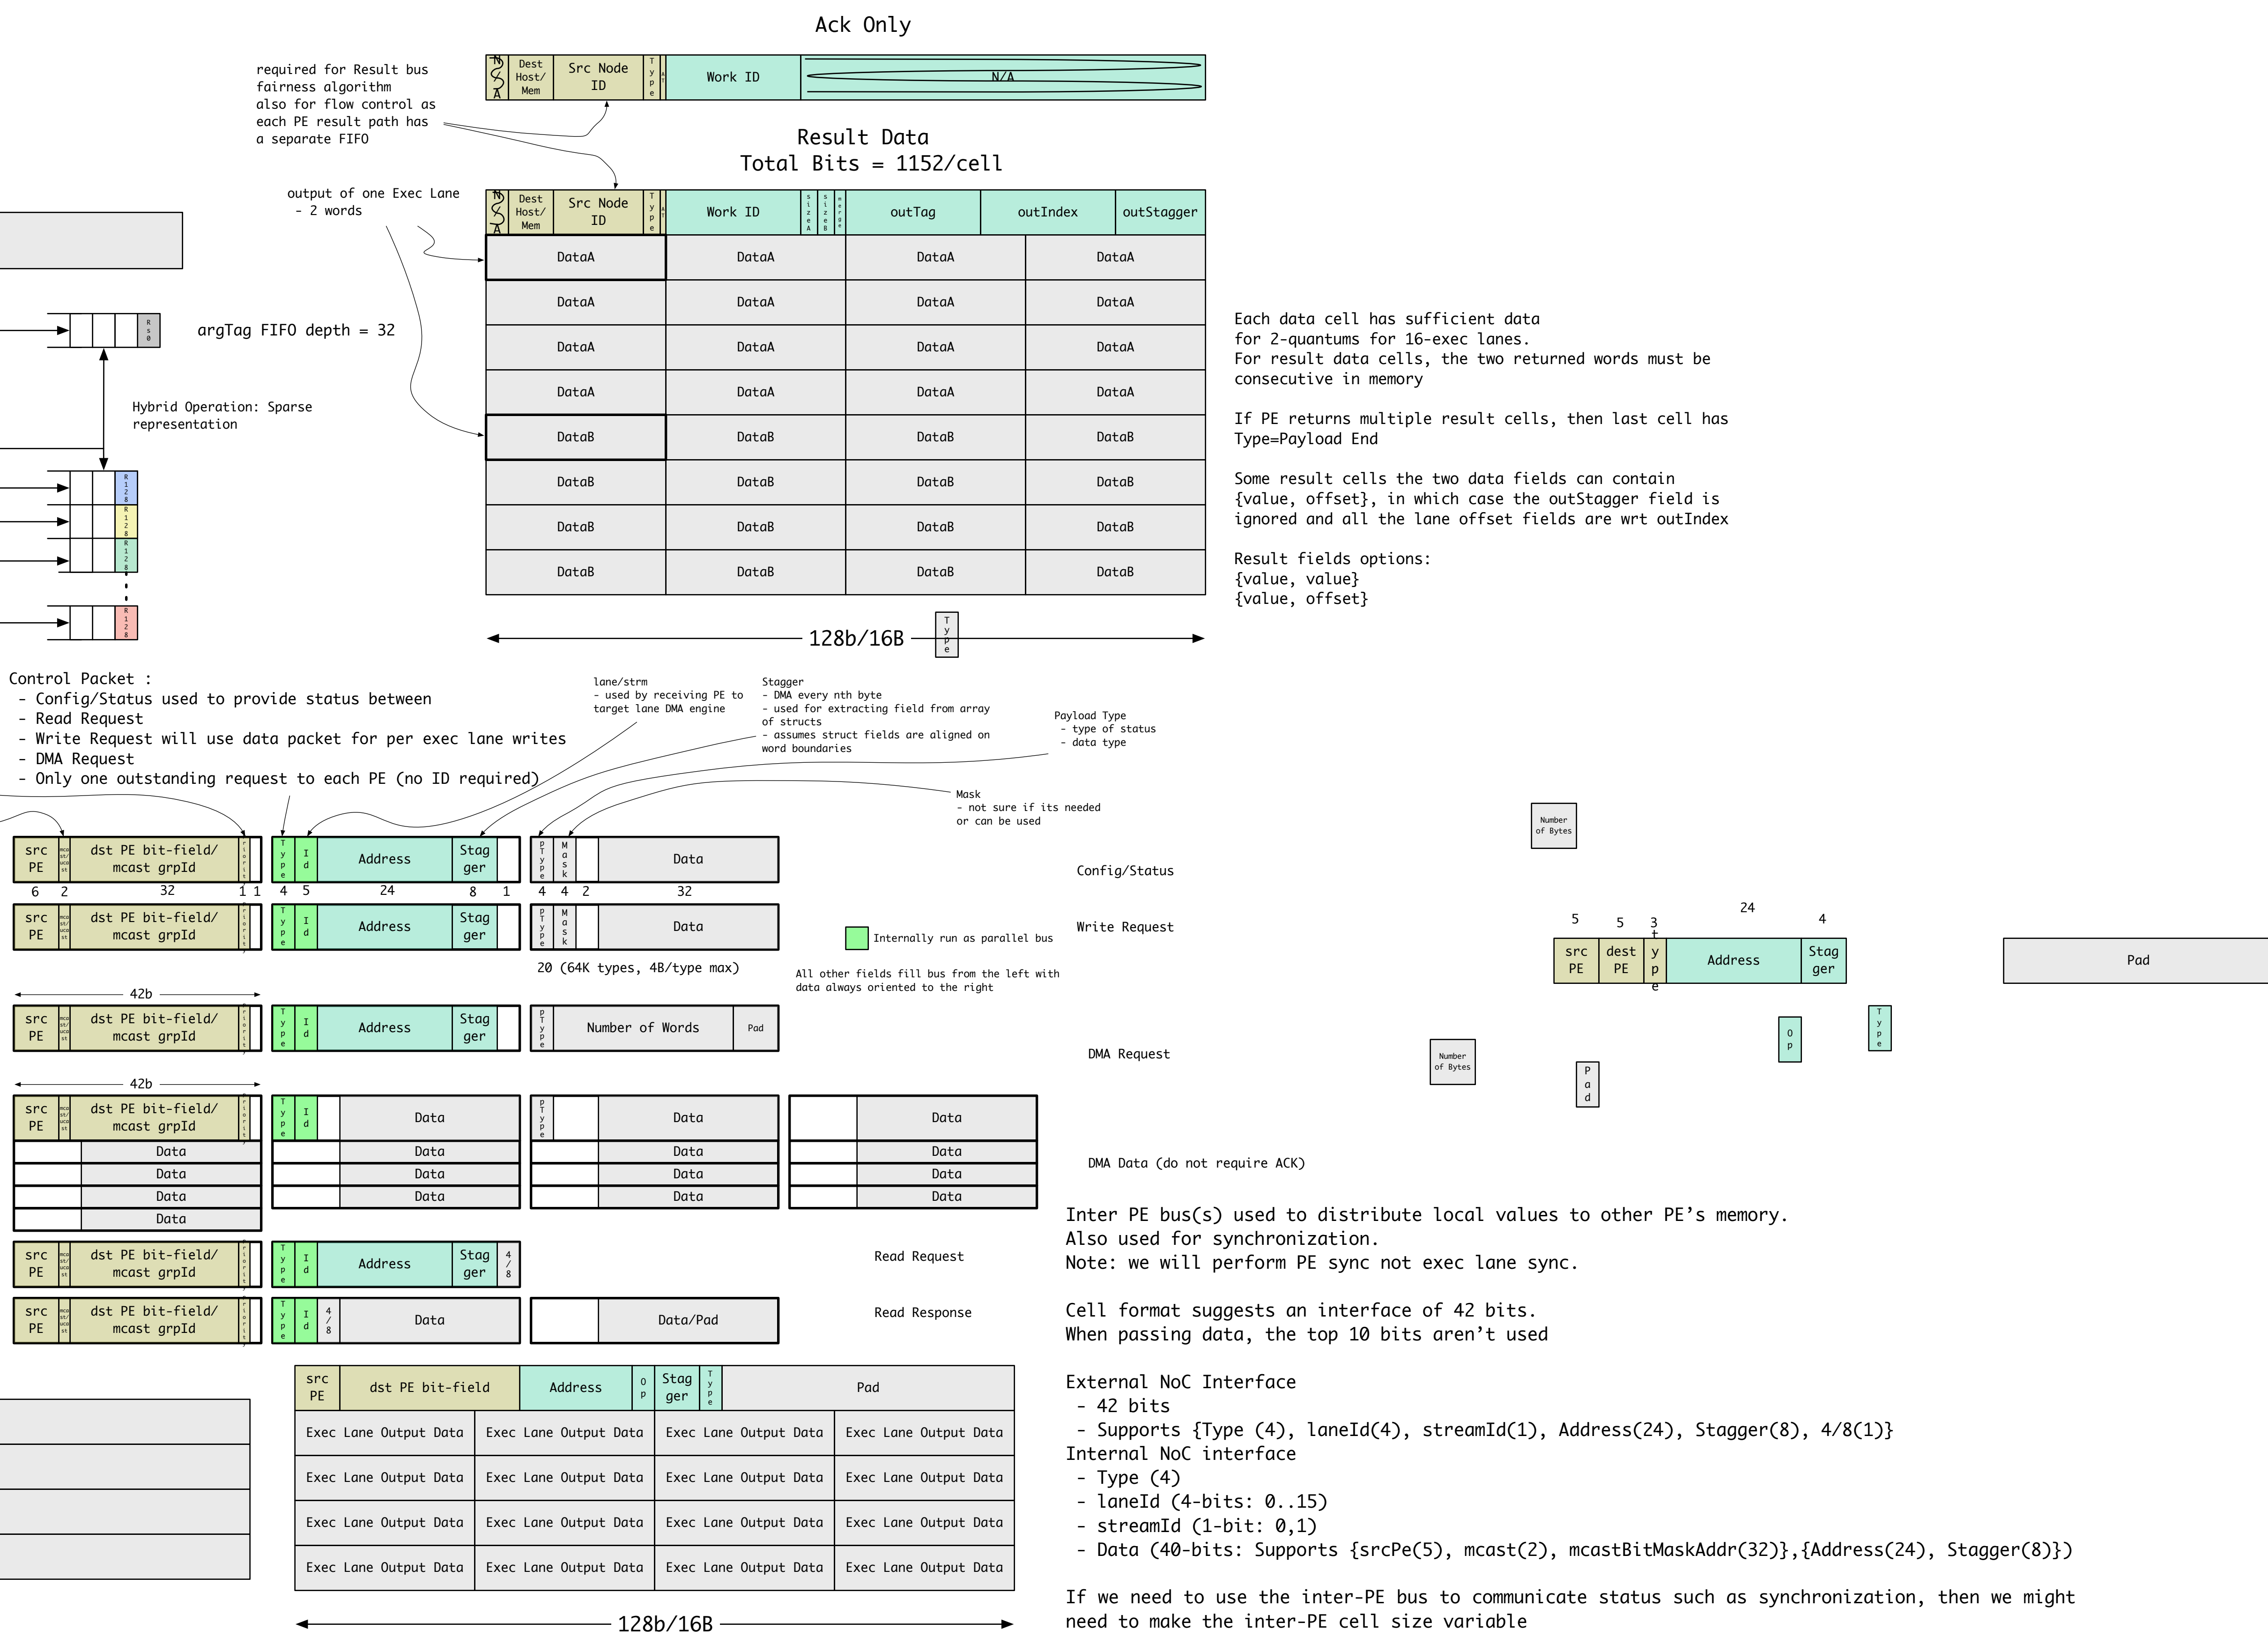

Each data cell has sufficient data for 2-quantums for 16-exec lanes, 1-quantum for 32-exec lanes

Inter-PE Comm Cells

Inter PE Data Packet :

- as a result of a WU directive
- as a result of a write or read request
- DMA request

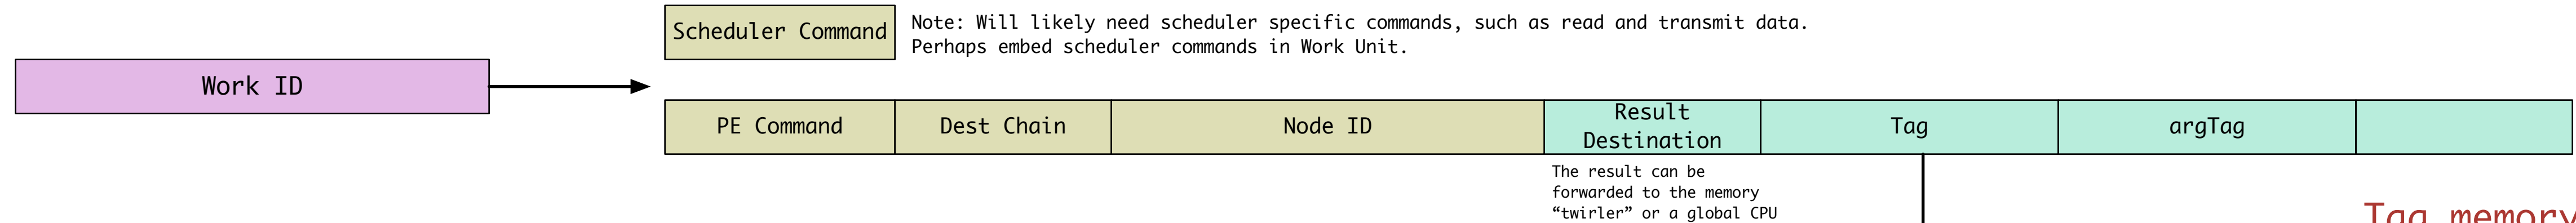

Layers are constructed from a list of work elements.
When all the work elements are complete, the layer is complete.

Work memory : a list of work elements.

In the case of sparsey or ConvNet, they can be ROI's or Kernels.
For Sparsey, we might have 100 MAC's with 1000 cells resulting in 100,000 WID's for layer0.
For ConvNet, we might have 96 kernels each operating on an ROI
Each WID specifies Tag for Cell weight matrix and argTag for the ROI

Sparsey: 100,000 MAC's.
BU Input ~ 192b = 24
H Input ~ 5000b = 156.25b

Example Sizes

Number of Chains	4
Dest Chain Size	2
Number of nodes	16
Nodes per chain	4
Node ID Size	2
Tag Address Size	17
Out Index Size	14

128Kx85

Tag memory : Indexed by Tag ID and argTag ID

Each Tag will represent an ROI, a Kernel or a weight matrix.

In sparsey, in layer 1 we will have 100 MAC with 1000 cells per MAC resulting in 100,000 weight matrices. Additional tag's would cover ROI's, say another 100.

For ConvNet, we might have 256 kernels and 100 ROI's.
